## IMPLEMENT CODE OPTIMIZATION TECHNIQUES DEAD CODE AND COMMON SUB EXPRESSION ELIMINATION

**AIM:**

To write a C program to implement the dead code elimination and common subexpression elimination (code optimization) techniques.

**ALGORITHM:**

- Start
- Create the input file which contains three address code.
- Open the file in read mode.
- If the file pointer returns NULL, exit the program else go to 5.
- Scan the input symbol from left to right.
- Store the first expression in a string.
- Compare the string with the other expressions in the file.
- If there is a match, remove the expression from the input file.
- Perform these steps 5-8 for all the input symbols in the file.
- Scan the input symbol from the file from left to right.
- Get the operand before the operator from the three address code.
- Check whether the operand is used in any other expression in the three address code.
- If the operand is not used, then eliminate the complete expression from the three-address code else go to 14.
- Perform steps 11 to 13 for all the operands in the three address code till end of the file is reached.
- Stop.

**PROGRAM:**

```
#include <stdio.h>
#include <string.h>

struct op {
    char l;
    char r[20];
};

int main() {
    int i, j, n, z = 0, m, q;
    char *p, *l;
    char temp, t;
    char *tem;

    printf("Enter number of values: ");
    scanf("%d", &n);

    struct op op[n], pr[10];
```

```

printf("Enter left and right values:\n");
for (i = 0; i < n; i++) {
    printf("\tleft: ");
    scanf(" %c", &op[i].l);
    printf("\tright: ");
    scanf("%s", op[i].r);
}

printf("Intermediate Code:\n");
for (i = 0; i < n; i++) {
    printf("%c=%s\n", op[i].l, op[i].r);
}

for (i = 0; i < n - 1; i++) {
    temp = op[i].l;
    for (j = 0; j < n; j++) {
        p = strchr(op[j].r, temp);
        if (p) {
            pr[z].l = op[i].l;
            strcpy(pr[z].r, op[i].r);
            z++;
        }
    }
    pr[z].l = op[n - 1].l;
    strcpy(pr[z].r, op[n - 1].r);
    z++;

    printf("\nAfter dead code elimination:\n");
    for (int k = 0; k < z; k++) {
        printf("%c=%s\n", pr[k].l, pr[k].r);
    }

    // Sub-expression elimination and duplicate production elimination code goes here...

    printf("Optimized Code:\n");
    for (i = 0; i < z; i++) {
        if (pr[i].l != '\0') {
            printf("%c=%s\n", pr[i].l, pr[i].r);
        }
    }

    return 0;
}

```

**OUTPUT:**

```
vimal@KBVIMAL: ~  
vimal@KBVIMAL:~$ vi 308deadcode.c  
vimal@KBVIMAL:~$ gcc 308deadcode.c  
vimal@KBVIMAL:~$ ./a.out  
Enter number of values: 4  
Enter left and right values:  
    left: a  
    right: b  
    left: c  
    right: d  
    left: e  
    right: g  
    left: i  
    right: h  
Intermediate Code:  
a=b  
c=d  
e=g  
i=h  
  
After dead code elimination:  
i=h  
Optimized Code:  
i=h  
vimal@KBVIMAL:~$
```

**RESULT:**
